the required power, voltage and welding current can also be decreased (a 7-mm arc requires 160 amp, 17 v and 2.65 kw-sec/cm, whereas a 2-mm arc needs 240 amp, 12 v and 1.73 kw-sec/cm). The short-arc method, however, can only be used in combination with the new split-type nozzle. For further improvement of the metal structure the cooling of the tube (internally and externally) must be intensified. To remove the cinder and the metal layer in which part of the alloying elements burnt out during welding, the tube is passed between two metal brushes (120 and 200 mm in diameter, with 0.3 - 0.5 mm diameter wires) applied before the calibrating stand, working at an 18 and 30 m/sec rate. To ensure an accurate fitting of the tube edges, the welding rolls are now being made of Г 13 (G13) non-magnetic and highly wear-resistant steel, which eliminates the magnetic effect of conventional steels. The strip width has also been reconsidered with regard to the new method and a formula is given for its calculation. By decreasing the strip-width, it is not necessary to raise the reduction on the calibrating stand. There are 3 figures.

Special features of stainless steel production

dovatel'skiy institut chernykh metallov (Ural Scientific Research Institute of Ferrous Metals) tests were carried out to clean the strip surface by means of ultrasound, the strip being led through a water bath, over which magnetostrictive vibrators are mounted, irradiating both strip surfaces with a 1.5 mm gap between vibration surface and the strip. The cleaning of the strip is completed with abrasive plates (80 x 50 mm) mounted before the ultrasound unit. The plates are continuously supplied with a hot alkaline solution. At a 1.1 m/min rolling rate the strip is subjected to cleaning by the alkaline abrasives for 3, in the ultrasound unit for 4 - 4.5 sec. To improve the welding process, a new split-type nozzle, with a 22 x 8 mm opening has been constructed for feeding the shielding gas. Under the new system the smelted metal is 3.5 times longer in the gas atmosphere than in the conventional method, ensuring a cleaner and denser seam, as the liquid weld solidifies under gas pressure. Tests are now being made with two nozzles, i.e., a shielding atmosphere is also produced within the tube by introducing another nozzle. It was also found that shortening the length of the arc resulted in a smaller part of the edges being heated, thus reducing the area of the liquid weld and, in general, the zones subjected to heat. This also increases the metal resistance to intergranular corrosion; moreover, in this case

AUTHORS: Grinberg, Z.A., Morozov, N.F., Gazman, S.M.

TITLE: Special features of stainless steel production in an atmosphere of inert gases

PERIODICAL: Stal', no. 2, 1963, 152 - 155

TEXT: The Pervoural'skiy starotrubnyy zavod (Pervoural'sk Old Tube Plant) has taken measures to prevent the intergranular corrosion of argon-arc welded stainless steel tubes. To eliminate the contamination of the strip surface no fat-containing emulsion is applied to the roll surface. This, of course, necessitated a smaller allowance for the rolls (+0.05 mm at the groove profile). Two metal brushes (220 mm in diameter, with 0.3 - 0.5 mm diameter wires) are mounted after the welding machine; before this the strip edges are polished by a 120-mm diameter metal brush (its motor operates with 1.5 kW and at 2,870 rpm). The strip thus enters the welding apparatus free of burrs and grease on its surface and with polished edges which improves the stability of the arc and prevents contamination of the liquid weld. In cooperation with the Ural'skiy nauchno-issledovatel'skiy institut po metallovedeniiu i posredstvam (Ural'skiy Scientific Research Institute of Metallurgy and Alloys) a new method of welding stainless steel strips has been developed.

TITLE: Centrifugal Casting of Cast-iron Water Pipes in Sand-lined Moulds (Tsentrobelzhuje otlivki v zashchitnykh vodoprovodnykh trub v peschano-futerovannyye formy)

PERIODICAL: Metallurg, 1958, Nr 8, pp 31 - 33 (USSR)

ABSTRACT: At the Pervouralskiy starotrubnyy Works, work has been going on since 1956 on the centrifugal casting of 2-inch diameter, 3.1 m long tubes in green sand moulds. For this, a special machine (Figure 1) has been constructed at the works, among whose special features are the provision of a device for tilting the moulds to 1.5° before filling and a brake for stopping rotation. For making the lining, a horizontal piston-screw machine (Figure 2) designed by Ya.M. Semenov, S.N. Bogorad and A.D. Dronov has been adopted. This machine has a lifting load of 27.5-ton and thick lining and experiments are proceeding with 18-mm thick linings. The productivity of the casting machine is 20 tubes per lot hour. The whole experimental installation (1 piston-screw machine and 10 centrifugal machines) has produced over 400 tons of sound tubes. It is thought that a revision of the

grease. This grease covers easily the pipe and leaves a thin layer facilitating the drawing. With the use of this grease pipe oiling can be centralized, the coefficient of extrusion can be raised to 1.7 per one pass, and double drawing can be performed at the surface, without annealing and with a total extrusion coefficient up to 1.4.

AUTHOR: Grinberg, Z.A.

TITLE: Drawing of steel pipes without drying

PERIODICAL: Referativnyy zhurnal. Metallurgiya, no. 3, 1961, p. 37. Abstract 3D393
("Tr. Nauchno-tekhn. o-va Chern. metallurgii", v. 19, 1960, 106-112)

TEXT: An investigation was made to reveal the effect of different temperatures during etching on the hydrogen or etching brittleness of metal. It was revealed that the admixture of ferrous metal protects the pipes in a sufficiently reliable manner against etching brittleness during etching in hydrochloric acid of 18°Be density and $30 - 40^{\circ}\text{C}$ temperature. In this connection the necessity of a special drying the pipes is eliminated, and the drying is performed at $130-150^{\circ}\text{C}$ for 1 hour. It must however, be borne in mind that the presence of moisture on the surface of non-dried pipes excludes the possibility of applying oil or plastic greases during drawing. Consequently, such pipes must be drawn with the loss of moisture containing emulsion greases. Good results are obtained with emulsions containing 12 - 15% soap graphite, 3 - 4% soap and 82 - 85% water. The author experiments are being carried out for the production of a new steel grade.

assigned special tasks. For two years the industrial training of the 144th school was carried out at the Zavod radiotekhnicheskikh priborov (Radiotechnical Device Plant). At present 1958/59 it is performed at the Moscow plant "Izolyator", which produces lead-ins, condensers and other items for the electrotechnical industry. At this plant the trainees have to get acquainted with the full production cycle and the organisation of the plant (electric shop, electric welding department, transport section, mechanical repair shop, galvanic shop). The main principles ruling this training, as set forth by the authors, are the following: 1) impart to the trainees some habits and skills in practical work and get them accustomed to working under industrial conditions; 2) give the trainees an idea of the general foundations of socialist industrial production; 3) show the application of scientific knowledge

TITLE: Relating Courses in Physics to Industrial Practice

PERIODICAL: Fizika v shkole, 1959, Nr 3, pp 27-31 (USSR)

ABSTRACT: This is a survey of practical training in physics received by pupils of school 144 in Moscow. Practical training begins in the 6th class. The pupils visit the plant, where later on (9th class) they will do practical work, and the teachers illustrate the subject of the lessons with examples taken from plant practice. The work to be performed at the plant in the 9th class extends over approximately 200 hours. In the course of a training year, the participants work at the plant once a week for 4 hours, and after the termination of the school year there follows a continuous practice of 12 days. During his training, each participant works at two places, where he is

Morphological and biochemical changes in the bulk of erythrocytes in different layers of glucose-citrate preserved blood. Yu. A. Grinberg, Z. S. El'yankevich, and R. I. Lantman—Transfusion Inst., Kiev). Ukrin. Biokhim. Zhurn. 21, No. 7 (in Russian) 279 (1969).—Ten ml. of 5% Na citrate, 1 ml. of 20% glucose, and 0.1 g. Na sulfathiazole were added to each 100 ml. blood. Densitograms of the degree of original and later masked hemolysis, of the osmotic resistance of the erythrocytes, of the morphology of red and white cells, and of leucocytes. Tests were made 15 min. and 2, 5, 10, 15, 20, 25, 30, and 35 days after taking the blood. Masked hemolysis in the lower layer of blood preserved in a vertical position after 15-30 days is more intense than in the upper layer (up to 7.8%). Changes in osmotic resistance, morphology, and biochemical properties in the cells of the upper and lower layers showed only slight differences. The products of hemolyzed leukocytes and thrombocytes and their enzymes have no effect upon the erythrocytes of preserved blood. Glucose-citrate blood for transfusion or study purposes should be preserved in shallow layers in large-diam. vessels. B. S. Levine

3661. IMPROVED STAND FOR AMPOULES USED FOR THE STORAGE OF
D. NORS' BLOOD (Russian text) - Grinberg E. A. - VRACH. DELO
1956, 9 (993-994)

An alteration is suggested in the construction of the stand used to hold ampoules when taking blood from donors. The new stand allows the angle of inclination of the ampoules to be changed, while special springs fitted in the base confine the angle within safe limits. In the upper part of the stand is a box for the ampoules, in which they can be corked without needing to be withdrawn. (S)

Treatment of acute experimental dysentery in rabbits by transfusion of fresh citrated blood. G. I. Chomenko and E. A. Grinberg (*Izv. Akad. Med. Ukraine*, 1940, 10, 127-137). Intravenous injection of 0.8 c.c. of an emulsion of Shiga-Kruze bacilli into rabbits produces acute dysentery to which the animals succumb in 3-4 days; the nervous system is affected during the first hr. after infection. Transfusion of fresh citrated blood within 30 min. of the infection was life-saving in 60% of animals; it was ineffective if performed 24 hr. after the infection. Large doses of antidyenteric serum injected during the first 3 hr. of the infection were more effective than blood transfusion. M. K.

Title : Standard engineering methods for production of petroleum equipment and steam boilers

Periodical : Vest. mash. 35/6, 35 - 41, Jun 1955.

Abstract : Standard engineering methods employed in production of petroleum equipment and steam boilers at "Ordzhonikidze" Machine Construction Factory in Podol'sk, are discussed. Approximately 160 types of equipment, of from 2-100 m long, 500-6400 mm in diameter, 4-36 mm thick, and weighing 0.5-200 tons, are produced at the above mentioned factory. Gas-cutting heads and apparatus for cutting boiler shells, edging and welding devices, and several types of welding apparatus, are described. Illustrations; drawings; tables.

TITLE: Study of the equilibrium in the boron phosphide - iodine system

SOURCE: AN SSSR. Izvestiya. Neorganicheskiye materialy, v. 2, no. 12, 1966, 2130-2133

TOPIC TAGS: boron compound, phosphide, iodine, chemical equilibrium

ABSTRACT: The heterogeneous equilibrium between solid boron phosphide and gaseous iodine was studied at 1075, 1120, 1160 and 1195°C. The amount of phosphorus and boron in the gas phase were determined from the weight loss of the solid phase, and the amount of iodine introduced was known. Assuming the equilibrium reaction to be $2\text{BPs} + \text{BI}_3 \rightleftharpoons 3\text{BI}_2 + \text{P}_2\text{g}$, the authors calculated the equilibrium constant K_p of this reaction, $K_p = [p_{\text{BI}}]^3 p_{\text{P}_2\text{g}} / p_{\text{BI}}$. Within the limits of experimental error, K_p thus calculated for all four temperatures had the same value, and its temperature dependence is given by the equation $\log K_p = -19,210/T + 10.59$ (atm³), i. e., in the temperature range studied $\log K_p$ varies linearly with reciprocal temperature. The enthalpy ΔH and entropy ΔS of the reaction per mole of BP were found to be 44 kcal/mole and 24 cal/

TITLE: Kinetics of the reaction of amorphous boron with phosphorus 27

SOURCE: AN SSSR. Izvestiya. Neorganicheskiye materialy, v. 1, no. 9, 1965, 1484-1492

TOPIC TAGS: rectifier⁴⁵, maser⁴⁵, semiconductor, boron phosphide, boron compound, kinetics, reaction mechanism

ABSTRACT: Boron phosphide (BP) is of considerable interest since rectifiers made from it can function in an oxidizing atmosphere at up to 1000°C. Boron phosphide monocrystals may prove useful for the design of masers and similar devices. In this work, the reaction of boron with phosphorus vapor was studied at 1000, 1100, and 1150°C. It was found that the reaction is initially rate controlled and follows second-order kinetics. Following a transition period, the reaction becomes diffusion controlled and obeys first-order kinetics. The latter stage of the reaction is presumably caused by the formation of a coating on the boron. The rate constants and activation energies of both reaction stages were determined. A mechanism is proposed for the reaction. The optimum quality of BP (< 10⁻³% Si) was obtained when the reaction was conducted at 1150—1200°C for 1 hr or less, using amorphous boron. higher ΔT , the number of nucleation sites increased sharply. Preferentially tabular or dendritic growth at higher temperatures (at constant ΔT) and well-developed, bulk single crystals of varied and complex habit at lower temperatures were observed. X-ray diffraction patterns showed the crystals had ZnS-type cubic symmetry. All the crystals had an n-type electric conductivity. The thermal emf in the 20--150°C range and the microhardness of the crystals were determined. Orig. art. has: 3 figures. [JK]

TITLE: Preparation of boron-phosphide single crystals from the vapor
phase

SOURCE: AN SSSR. Doklady, v. 160, no. 2, 1965, 337-338

TOPIC TAGS: single crystal growth, boron phosphide, vapor phase
growth, chemical transport reaction, semiconductor boron phosphide

ABSTRACT: Single crystals of pure (99.998%) boron phosphide have
been prepared by a chemical transport reaction in the vapor phase
to avoid the difficulties encountered in preparing perfect single
crystals by sublimation. The reaction was conducted in vacuum with
an element [unspecified] of the sixth group of the periodic system,
which forms a volatile compound with boron. The effects of the tem-
perature gradient (ΔT) in the reaction volume, and of the temperature
in the crystallization zone in the 900-1200°C range, were studied;
the most perfect single crystals were formed at $\Delta T = 20-40^\circ\text{C}$. At

ABSTRACT: Synthesis of high-purity (99.998%) microcrystalline boron phosphide powder and a technique of growing boron phosphide single crystals have been developed to produce crystals of the purity and size suitable for measurement of physical characteristics. Difficulties encountered in preparation of this refractory compound semiconductor were emphasized. The purity achieved by the process described was almost an order of magnitude higher than in previous preparations. A chemical transport reaction with iodine vapors was used for growing the single crystals. The reaction involving a diffusion mechanism produced 1-1.5-mm large crystals. Morphology of the crystals was described and x-ray crystallographic data were given. Microhardness of the crystals was measured and found to be somewhat different than

TITLE: Research on the transfer of boron phosphide during a transport reaction

SOURCE: AN SSSE. Izvestiya. Neorganicheskiye materialy, v. 1, no. 1, 1965, 88-90

TOPIC TAGS: boron phosphide, boron transfer, transport reaction, single crystal, diffusion

ABSTRACT: Considering the problem of reactions in which the product must not mix with the reactants, and where even temperature differences must be maintained, the authors extended their research on the method developed by H. Schafer. The reaction was produced in a quartz ampoule 150-200 mm in length, 20 mm max. width, evacuated to 10^{-5} mm Hg, loaded with powdered boron phosphide of 99.998% purity (prepared from boron and phosphorus vapor at 4.5 atm. pressure) and a carrier element from Group VI of the periodic table. The temperature in the ampoule was controlled to an accuracy of $\pm 5^\circ\text{C}$, and the partial pressure of the carrier was held at 5-200 mm Hg. The temperatures used were T_1 between 1203 and 1300K and T_2 between 1355 and 1393K. It was established that at these temperatures and pressures the basic mass transfer mechanism was diffusion. Over the range of the experiment, there was

TITLE: Thermodynamics of boron phosphide BP

SOURCE: Zhurnal neorg. khim. v. 9, no. 2, 1964, 491

TOPIC TAGS: boron phosphide, boron phosphide preparation, thermodynamics

ABSTRACT: This study has been conducted to complete and verify thermodynamic data from literature. The formation of boron phosphide, a potential semiconductor, by reacting a boron halide with a phosphorus halide in an atmosphere of helium and hydrogen at temperatures of 1200C or above was found to proceed according to the global equation:

The heat and free energy of formation of BP at 1200C were determined.

of South America) and the other in the South of the Sargasso Sea. Table 1 shows the measurement results of submarine illumination. It varies considerably. It may be strongly reduced by the strong development of the phytoplankton. In figure 1 data are compared to each other which characterize the change of the coefficient of the photosynthesis rate $K_T(1)$ due to

submarine illumination η (2) with the depth. Down to a certain depth there is an inverse dependence between these two values, i. e. photosynthesis is suppressed in the surface layer. Photosynthesis attains its maximum where the illumination amounts to 30-50% of the illumination on the surface. This is the optimum depth for algae. In the north-western part of the Pacific and in the Japan Sea (route of the ship "Vityaz") photosynthesis is not suppressed in the upper layer. It may be seen from figure 1 that the rate of photosynthesis in the layer suppressed by light is inversely dependent on submarine illumination. Suppression takes place in the open ocean down to a depth of 20-40 m, in the littoral down to 5-10 m.

Card 3/4

On the Determination of the Dependence of the Photo-synthesis of the Phytoplankton on Submarine Illumination in the Central Part of the Atlantic Ocean

between the illumination at the depth z and that on the surface z^0 . The method of determination mentioned in the title is described in reference 1: The water is carried in glasses from a certain horizon, a constant amount of radioactive carbonate $\text{Na}_2\text{C}^{14}\text{O}_3$ is added and the glasses are then again submerged for 1/2 or 1 day to depths of 0, 10, 30, 50, 75, 100, and 150 m. Except in the case of a depth of 150 m also the illumination was measured in these horizons. The algae which live in the water carry the radioactive carbon C^{14} from the carbonate into the organic substance of their organisms. The residue after filtration of water from the glasses on a membrane filter is measured by a counter. Its radioactivity shows the amount of C^{14} containing carbonate assimilated during the experiment. From this the assimilated amount of CO_2 is computed and the primary production is determined for a certain water volume. The stations which carried out these investigations are situated on the western coast of Africa, one on the equator (on the northern coast

ABSTRACT:

On the expedition ship "Sedov" investigations of the primary
production of the organic substance by phytoplankton were
carried out by means of photosynthesis in March - June 1958
within the framework of oceanographic standard works. Observa-
tions concerning a) the submarine illumination and b) the
primary production of the organic substance mentioned served
as starting material. a) For this purpose a photoelectric
measuring device FMPO-57 was used in depths of 0 to 100 m.
The device is described. In order to characterize the pen-
etration of light into the depth at each station, coefficients
of the submarine illumination (h) were computed on the relation
